Abstract

We construct the CP-odd weak basis invariants from the neutrino mass matrix in a weak basis in which the charged lepton mass matrix is diagonal and find the necessary and sufficient conditions for CP conservation. We study the interrelationships between different CP-odd weak basis invariants to examine their implications for the Dirac and Majorana type CP violating phases for the phenomenologically allowed Frampton-Glashow-Marfatia texture zero structures of the neutrino mass matrix.

1 Introduction

In the Standard Model (SM) of fundamental particles and interactions, there is no CP violation in the leptonic sector. However, in most extensions of the SM, there can be several CP violating phases. In the simplest three generation scenario, there is a Dirac type CP violating phase in the lepton mixing matrix. However, for Majorana neutrinos, there could be two additional phases. It is possible to work in a parametrization in which all the three CP violating phases are situated in the charged current lepton mixing matrix. Without any loss of generality, one can work in flavor basis in which charged lepton mass matrix is diagonal so that the neutrino mass matrix carries all the information about CP violation. The search for CP violation in the leptonic sector at low energies is one of the major challenges for experimental neutrino physics. Experiments with superbeams and neutrino beams from neutrino factories have the potential to measure either directly the Dirac phase δ through the observation of CP and T asymmetries or indirectly through neutrino oscillations. An alternative method is to measure the area of the unitarity triangles defined for the leptonic sector. Thus, neutrino physics provides an invaluable tool for the investigation of leptonic CP violation at low energies apart from having profound implications for the physics of the early universe.

In the flavor basis, the mass matrix for Majorana neutrinos contains nine physical parameters including three mass eigenvalues, three mixing angles and three CP violating phases. Two squared mass differences (Δm_{12}^2 and Δm_{13}^2) and two mixing angles (θ_{12} and θ_{23}) have been measured in solar, atmospheric and reactor experiments. The third mixing angle θ_{13} and the Dirac type CP violating phase δ are expected to be measured in the forthcoming neutrino oscillation experiments. Possible measurement of effective Majorana mass in neutrinoless double beta decay searches will provide an additional constraint on the remaining three neutrino parameters viz. neutrino mass scale and two Majorana type CP violating phases. While the neutrino mass scale will be independently determined from the direct beta decay searches and cosmological observations, the two Majorana phases will not be uniquely determined from the measurement of effective Majorana mass even if the overall neutrino mass scale is known. Thus, it is not possible to fully reconstruct the neutrino mass matrix from the observations from feasible experiments. Under the circumstances, it is natural to employ other theoretical inputs for the reconstruction of the neutrino mass matrix. The possible forms of these additional theoretical inputs are constrained by the existing neutrino data. Several proposals have been made in literature to restrict the possible forms of the neutrino mass matrix by reducing the number of free parameters which include the presence of texture zeros [1, 2, 3], the requirement of zero determinant [4], the zero trace condition [5] amongst others.

There have been numerous attempts aimed at understanding the pattern of the fermion masses and mixings by introducing Abelian and non-Abelian flavor symmetries some of which lead to texture zeros in the fermion mass matrices. Furthermore, as discussed earlier, it is not possible to fully reconstruct the neutrino mass matrix solely from the results of presently feasible experiments and the introduction of texture zeros is an extra ingredient aimed at reducing the number of free parameters. However, some sets of these texture zeros can be obtained by suitable weak basis transformations and have no physical meaning as such. However, a large class of sets of leptonic texture zeros considered in the literature imply the vanishing of certain CP-odd weak basis invariants and one can, thus, recognize a lepton flavor model in which the texture zeros are not explicitly present but which corresponds to a particular texture structure in a certain weak basis. The presence of texture zeros, in general, leads to a decrease in the number of independent CP violating phases. A particular texture zero structure gives rise to definite relationships between different CP violating phases [2]. Such exact relations in closed form were obtained in Ref. [6]. Correlations between Dirac and Majorana CP violating phases for a particular texture zero scheme were studied in detail in Ref. [2]. It is, therefore, important to examine the interrelationships between the CP odd weak basis invariants which are required to vanish as a necessary and sufficient condition for CP conservation. It is the purpose of the present work to examine systematically such interrelationships in terms of the weak basis invariants constructed from the elements of the neutrino mass matrix.

2 Weak basis invariants from the neutrino mass matrix

The texture zeros are not weak basis (WB) invariants [7]. This means that a given set of texture zeros which arise in a certain WB may not be present or may appear in different entries in another WB. A large class of sets of leptonic texture zeros considered in the literature imply the vanishing of certain CP-odd weak-basis invariants [7]. Thus, we can recognize a lepton mass model in which the texture zeros are not explicitly present and which corresponds to a particular texture scheme in

a certain WB. The relevance of CP-odd WB invariants in the analysis of the texture zero ansatz is due to the fact that texture zeros lead to a decrease in the number of the independent CP violating phases. A minimum number of CP-odd WB invariants can be found which will all vanish for the CP invariant mass matrices as a necessary and sufficient condition [8].

A necessary and sufficient condition for low energy CP invariance in the leptonic sector is that the following three WB invariants are identically zero [9]:

$$I_1 = \text{Im}g \text{ Det}[H_\nu, H_l], \quad (1)$$

$$I_2 = \text{Im}g \text{ Tr}[H_l M_\nu M_\nu^* M_\nu H_l^* M_\nu^*], \quad (2)$$

$$I_3 = \text{Im}g \text{ Det}[M_\nu^* H_l M_\nu, H_l^*]. \quad (3)$$

Here, M_l and M_ν are the mass matrices for the charged leptons and the neutrinos, respectively, and $H_l = M_l^\dagger M_l$ and $H_\nu = M_\nu^\dagger M_\nu$. The invariant I_1 was first proposed by Jarlskog [10] as a rephasing invariant measure of Dirac type CP violation in the quark sector. It, also, describes the CP violation in the leptonic sector and is sensitive to the Dirac type CP violating phase. The invariants I_2 and I_3 were proposed by Branco, Lavoura and Rebelo [11] as the WB invariant measures of Majorana type CP violation. The invariant I_3 was shown [12] to have the special feature of being sensitive to Majorana type CP violating phase even in the limit of the exactly degenerate Majorana neutrinos.

The CP violation in the lepton number conserving (LNC) processes is contained in Jarlskog CP invariant J which can be calculated from the WB invariant I_1 using the relation

$$I_1 = -2J(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2)(m_1^2 - m_2^2)(m_2^2 - m_3^2)(m_3^2 - m_1^2) \quad (4)$$

if the neutrino mass matrix M_ν is a complex symmetric matrix with eigenvalues m_1 , m_2 and m_3 and the charged lepton mass matrix M_l is diagonal and given by

$$M_l = \text{diag}\{m_e, m_\mu, m_\tau\}. \quad (5)$$

Then, we have

$$I_1 = 2(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2) \text{Im}g (M_{ee}A_{ee} + M_{\mu\mu}A_{\mu\mu} + M_{\tau\tau}A_{\tau\tau}) \quad (6)$$

where the coefficients A_{ee} , $A_{\mu\mu}$ and $A_{\tau\tau}$ are given by

$$\begin{aligned} A_{ee} = & M_{\mu\tau}M_{e\mu}^*M_{e\tau}^*(|M_{\mu\mu}|^2 - |M_{\tau\tau}|^2 - |M_{e\mu}|^2 + |M_{e\tau}|^2) \\ & + M_{\mu\mu}M_{e\mu}^{*2}(|M_{e\tau}|^2 - |M_{\mu\tau}|^2) \\ & + M_{\mu\mu}^*M_{e\tau}^{*2}M_{\mu\tau}^2, \end{aligned} \quad (7)$$

$$\begin{aligned} A_{\mu\mu} = & M_{e\tau}M_{\mu\tau}^*M_{e\mu}^*(|M_{\tau\tau}|^2 - |M_{ee}|^2 - |M_{\mu\tau}|^2 + |M_{e\mu}|^2) \\ & + M_{\tau\tau}M_{\mu\tau}^{*2}(|M_{e\mu}|^2 - |M_{e\tau}|^2) \\ & + M_{\tau\tau}^*M_{e\mu}^{*2}M_{e\tau}^2 \end{aligned} \quad (8)$$

and

$$\begin{aligned} A_{\tau\tau} = & M_{e\mu}M_{e\tau}^*M_{\mu\tau}^*(|M_{ee}|^2 - |M_{\mu\mu}|^2 - |M_{e\tau}|^2 + |M_{\mu\tau}|^2) \\ & + M_{ee}M_{e\tau}^{*2}(|M_{\mu\tau}|^2 - |M_{e\mu}|^2) \\ & + M_{ee}^*M_{\mu\tau}^{*2}M_{e\mu}^2. \end{aligned} \quad (9)$$

Therefore, the Jarlskog CP invariant measure J is given by

$$J = \frac{\text{Im}g (M_{ee}A_{ee} + M_{\mu\mu}A_{\mu\mu} + M_{\tau\tau}A_{\tau\tau})}{(m_1^2 - m_2^2)(m_2^2 - m_3^2)(m_3^2 - m_1^2)}. \quad (10)$$

This relation can be used to calculate J from the mass matrices directly for any lepton mass model rotated to the WB in which M_l is diagonal.

The CP violation in lepton number violating (LNV) processes can be calculated from the WB invariants I_2 and I_3 which have been given below:

$$\begin{aligned} I_2 = \text{Im}g (M_{ee}M_{e\mu}^{*2}M_{\mu\mu}(m_e^2 - m_\mu^2)^2 + M_{\mu\mu}M_{\mu\tau}^{*2}M_{\tau\tau}(m_\mu^2 - m_\tau^2)^2 + M_{\tau\tau}M_{e\tau}^{*2}M_{ee}(m_\tau^2 - m_e^2)^2 \\ + 2M_{ee}M_{e\mu}^*M_{e\tau}^*M_{\mu\tau}(m_e^2 - m_\mu^2)(m_e^2 - m_\tau^2) \\ + 2M_{\mu\mu}M_{\mu\tau}^*M_{e\mu}^*M_{e\tau}(m_\mu^2 - m_\tau^2)(m_\mu^2 - m_e^2) \\ + 2M_{\tau\tau}M_{e\tau}^*M_{\mu\tau}^*M_{e\mu}(m_\tau^2 - m_e^2)(m_\tau^2 - m_\mu^2)) \end{aligned} \quad (11)$$

and

$$I_3 = 2(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2)\text{Im}g(m_e^2M_{ee}B_{ee} + m_\mu^2M_{\mu\mu}B_{\mu\mu} + m_\tau^2M_{\tau\tau}B_{\tau\tau}) \quad (12)$$

where the coefficients B_{ee} , $B_{\mu\mu}$ and $B_{\tau\tau}$ are given by

$$\begin{aligned} B_{ee} = M_{\mu\tau}M_{e\mu}^*M_{e\tau}^*(m_\mu^4|M_{\mu\mu}|^2 - m_\tau^4|M_{\tau\tau}|^2 - m_e^2m_\mu^2|M_{e\mu}|^2 + m_e^2m_\tau^2|M_{e\tau}|^2) \\ + m_\mu^2M_{\mu\mu}M_{e\mu}^{*2}(m_e^2|M_{e\tau}|^2 - m_\mu^2|M_{\mu\tau}|^2) \\ + m_\mu^2m_\tau^2M_{\mu\mu}^*M_{e\tau}^{*2}M_{\mu\tau}^2, \end{aligned} \quad (13)$$

$$\begin{aligned} B_{\mu\mu} = M_{e\tau}M_{\mu\tau}^*M_{e\mu}^*(m_\tau^4|M_{\tau\tau}|^2 - m_e^4|M_{ee}|^2 - m_\mu^2m_\tau^2|M_{\mu\tau}|^2 + m_e^2m_\tau^2|M_{e\mu}|^2) \\ + m_\tau^2M_{\tau\tau}M_{\mu\tau}^{*2}(m_\mu^2|M_{e\mu}|^2 - m_\tau^2|M_{e\tau}|^2) \\ + m_e^2m_\tau^2M_{\tau\tau}^*M_{e\mu}^{*2}M_{e\tau}^2 \end{aligned} \quad (14)$$

and

$$\begin{aligned} B_{\tau\tau} = M_{e\mu}M_{e\tau}^*M_{\mu\tau}^*(m_e^4|M_{ee}|^2 - m_\mu^4|M_{\mu\mu}|^2 - m_e^2m_\tau^2|M_{e\tau}|^2 + m_\mu^2m_\tau^2|M_{\mu\tau}|^2) \\ + m_e^2M_{ee}M_{e\tau}^{*2}(m_\tau^2|M_{\mu\tau}|^2 - m_e^2|M_{e\mu}|^2) \\ + m_e^2m_\mu^2M_{ee}^*M_{\mu\tau}^{*2}M_{e\mu}^2. \end{aligned} \quad (15)$$

From the above expressions for the WB invariants I_1 , I_2 and I_3 , one can immediately conclude that

1. A sufficient condition for CP conservation in LNC and LNV processes is that all the diagonal entries in the neutrino mass matrix vanish. Therefore, the symmetric neutrino mass matrices having Zee-type structure [5] in the diagonal charged lepton basis are CP conserving.

Type	Constraining Eqs.
A_1	$M_{ee} = 0, M_{e\mu} = 0$
A_2	$M_{ee} = 0, M_{e\tau} = 0$
B_1	$M_{e\tau} = 0, M_{\mu\mu} = 0$
B_2	$M_{e\mu} = 0, M_{\tau\tau} = 0$
B_3	$M_{e\mu} = 0, M_{\mu\mu} = 0$
B_4	$M_{e\tau} = 0, M_{\tau\tau} = 0$
C	$M_{\mu\mu} = 0, M_{\tau\tau} = 0$

Table 1: Allowed two texture zero mass matrices.

2. A sufficient condition for CP conservation in LNC processes is that any three independent entries in the neutrino mass matrix vanish. Therefore, the symmetric neutrino mass matrices having three texture zeros in the flavor basis cannot give CP violation in LNC processes. Such a mass matrix will have three independent phases and all of them can be rephased away by field redefinitions. However, some of the symmetric neutrino mass matrices having three texture zeros in the flavor basis can give CP violation in LNV processes since I_2 can be non-zero. The neutrino mass matrices having three zeros in a row or a column will have non-zero I_2 and, hence, will exhibit Majorana type CP violation with one physical phase.
3. The neutrino mass matrix with $\mu - \tau$ symmetry satisfying the relations

$$M_{e\mu} = \pm M_{e\tau} \text{ and } M_{\mu\mu} = M_{\tau\tau} \quad (16)$$

cannot give CP violation in LNC processes because $\text{Det} [H_\nu, H_l]$ vanishes if $\mu - \tau$ symmetry is present. However, unlike the LNC processes, the neutrino mass matrix with $\mu - \tau$ symmetry does not conserve CP in LNV processes since I_2 and I_3 do not vanish, in general, for the neutrino mass matrix with $\mu - \tau$ symmetry.

3 Implications for texture zeros

The seven allowed textures of the neutrino mass matrices with Frampton, Glashow and Marfatia (FGM) texture zero structure have been summarized in Table 1.

3.1 Class A

For neutrino mass matrices of type A_1 , we have

$$I_1 = 2|M_{e\tau}|^2(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2)\text{Im}g(M_{\mu\mu}M_{\tau\tau}M_{\mu\tau}^{*2}), \quad (17)$$

$$I_2 = (m_\mu^2 - m_\tau^2)^2\text{Im}g(M_{\mu\mu}M_{\tau\tau}M_{\mu\tau}^{*2}) \quad (18)$$

and

$$I_3 = 2m_\mu^2m_\tau^4|M_{e\tau}|^2(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2)\text{Im}g(M_{\mu\mu}M_{\tau\tau}M_{\mu\tau}^{*2}). \quad (19)$$

The WB invariants for class A_2 can be obtained by interchanging the μ and τ indices in the above relations.

An important conclusion follows from the above equations. The CP violation is brought about by the mismatch in the phases of $M_{\mu\tau}^2$ and $M_{\mu\mu}M_{\tau\tau}$ whereas the phase of the element $M_{e\mu}$ or $M_{e\tau}$ plays no role in the CP violation. In other words, the phase of the element $M_{e\mu}$ or $M_{e\tau}$ of the neutrino mass matrix has no physical significance in class A and it can be rephased away. However, a phase in the $\mu - \tau$ sector of the neutrino mass matrix is physical and cannot be rephased away. A rephasing transformation will only rotate the phase in the $\mu - \tau$ sector.

The neutrino mass matrices of class A have four non-zero independent elements and J is proportional to all of those four non-zero elements. Any of these four elements cannot vanish since this will create three texture zeros in the mass matrix making it incompatible with the existing neutrino data. Hence, a necessary and sufficient condition for $J = 0$ in a complex symmetric neutrino mass matrix is

$$2\arg(M_{\mu\tau}) = \arg(M_{\mu\mu}) + \arg(M_{\tau\tau}). \quad (20)$$

The condition given in Eq. (20) is equivalent to the condition that the neutrino mass matrix M can be factorized as $PM^{(r)}P$ where P is a diagonal phase matrix $\text{diag}\{e^{i\phi_1}, e^{i\phi_2}, e^{i\phi_3}\}$ and $M^{(r)}$ is a real matrix whose elements are real and equal in magnitude to the corresponding elements of M . Therefore, the necessary and sufficient condition for CP conservation is that the neutrino mass matrix M can be written as

$$M = PM^{(r)}P. \quad (21)$$

This equation is trivially satisfied for a real mass matrix. However, if the neutrino mass matrix is a general complex symmetric matrix, then it is not necessary that it satisfies Eqs. (20) or (21) and, therefore, it will be CP-violating, in general.

3.2 Class B

The neutrino mass matrices of class B can be divided into sub-classes on the basis of their CP behavior. In the first sub-class, we have the neutrino mass matrices of type B_1 and B_2 for which I_2 is zero. In the second sub-class, we have the neutrino mass matrices of type B_3 and B_4 for which I_2 is non-zero.

For neutrino mass matrices of types B_1 , we have

$$I_1 = 2(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2)\text{Im}g(M_{ee}^* M_{\mu\tau}^{*2} M_{e\mu}^2 M_{\tau\tau}), \quad (22)$$

$$I_2 = 0 \quad (23)$$

and

$$I_3 = 2m_e^2 m_\mu^2 m_\tau^2 (m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2)\text{Im}g(M_{ee}^* M_{\mu\tau}^{*2} M_{e\mu}^2 M_{\tau\tau}). \quad (24)$$

The WB invariants for neutrino mass matrices of type B_2 can be obtained by interchanging the μ and τ indices in the above relations.

Type	CP invariance condition
A_1	$2 \arg(M_{\mu\tau}) = \arg(M_{\mu\mu}) + \arg(M_{\tau\tau})$
B_1	$\arg(M_{ee}) + 2 \arg(M_{\mu\tau}) = \arg(M_{\tau\tau}) + 2 \arg(M_{e\mu})$
B_3	$2 \arg(M_{e\tau}) = \arg(M_{ee}) + \arg(M_{\tau\tau})$
C	$\arg(M_{ee}) + \arg(M_{\mu\tau}) = \arg(M_{e\mu}) + \arg(M_{e\tau})$

Table 2: Conditions for CP invariance for the neutrino mass matrices of class A, B and C.

For neutrino mass matrices of type B_3 , we have

$$I_1 = 2|M_{\mu\tau}|^2(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2) \text{Im}g (M_{ee}M_{\tau\tau}M_{e\tau}^{*2}), \quad (25)$$

$$I_2 = (m_e^2 - m_\tau^2) \text{Im}g (M_{ee}M_{\tau\tau}M_{e\tau}^{*2}) \quad (26)$$

and

$$I_3 = 2m_e^2m_\tau^4|M_{\mu\tau}|^2(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2) \text{Im}g (M_{ee}M_{\tau\tau}M_{e\tau}^{*2}). \quad (27)$$

The WB invariants for class B_4 can be obtained from the interchange of the μ and τ indices in the above relations.

The conditions for the CP invariance of neutrino mass matrices of class B have been summarized in Table 2. These conditions on the phases of the neutrino mass matrix can be viewed as the fine tunings required to have CP invariance.

3.3 Class C

For neutrino mass matrices of type C , we have

$$I_1 = 2(|M_{e\mu}|^2 - |M_{e\tau}|^2)(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2) \text{Im}g (M_{e\mu}^*M_{e\tau}^*M_{ee}M_{\mu\tau}), \quad (28)$$

$$I_2 = 2(m_e^2 - m_\mu^2)(m_\tau^2 - m_e^2) \text{Im}g (M_{e\mu}^*M_{e\tau}^*M_{ee}M_{\mu\tau}) \quad (29)$$

and

$$I_3 = 2m_e^4(m_\mu^2|M_{e\mu}|^2 - m_\tau^2|M_{e\tau}|^2)(m_e^2 - m_\mu^2)(m_\mu^2 - m_\tau^2)(m_\tau^2 - m_e^2) \text{Im}g (M_{e\mu}^*M_{e\tau}^*M_{ee}M_{\mu\tau}) \quad (30)$$

The neutrino mass matrix of class C will be CP invariant if the phases of the mass matrix are fine tuned to satisfy the condition

$$\arg(M_{ee}) + \arg(M_{\mu\tau}) = \arg(M_{e\mu}) + \arg(M_{e\tau}). \quad (31)$$

The CP violation structure of class C is much different from the CP violating structure of classes A and B. In class C, the quantity I_1 depends upon the difference between absolute squares of two

Type	$\frac{I_2}{I_1}$	$\frac{I_3}{I_1}$
A_1	$\frac{1}{2 M_{e\tau} ^2(m_e^2-m_\mu^2)(m_\tau^2-m_e^2)}$	$m_\mu^2 m_\tau^4$
A_2	$\frac{1}{2 M_{e\mu} ^2(m_e^2-m_\mu^2)(m_\tau^2-m_e^2)}$	$m_\mu^4 m_\tau^2$
B_1	0	$m_e^2 m_\mu^2 m_\tau^2$
B_2	0	$m_e^2 m_\mu^2 m_\tau^2$
B_3	$\frac{1}{2 M_{\mu\tau} ^2(m_e^2-m_\mu^2)(m_\mu^2-m_\tau^2)}$	$m_e^2 m_\tau^4$
B_4	$\frac{1}{2 M_{\mu\tau} ^2(m_\mu^2-m_\tau^2)(m_\tau^2-m_e^2)}$	$m_e^2 m_\mu^4$
C	$\frac{1}{(m_\mu^2-m_\tau^2)(M_{e\mu} ^2- M_{e\tau} ^2)}$	$\frac{m_e^4(m_\mu^2 M_{e\mu} ^2-m_\tau^2 M_{e\tau} ^2)}{ M_{e\mu} ^2- M_{e\tau} ^2}$

Table 3: Ratios $\frac{I_2}{I_1}$ and $\frac{I_3}{I_1}$ for class A, B and C neutrino mass matrices.

matrix elements $M_{e\mu}$ and $M_{e\tau}$ unlike other classes. So, I_1 will vanish if $M_{e\mu} = M_{e\tau}$. Since, we have $M_{\mu\mu} = M_{\tau\tau}$ in class C, this special case is $\mu - \tau$ symmetric. Hence, the neutrino mass matrices of class C having $\mu - \tau$ symmetry can not exhibit CP violation in LNC processes. However, they can exhibit CP violation in the LNV processes since I_2 and I_3 can be non-zero. In this special case, the neutrino mass matrix contains only a Majorana phase and there is no Dirac phase. This special case is important, therefore, in the sense that we can tell whether the physical phase in the mass matrix gives rise to CP violation in LNC or LNV processes.

The three WB invariants for neutrino mass matrices are related with one another in each class of neutrino mass matrices with FGM textures. The relations have been summarized in Table 3. Therefore, I_1 , I_2 and I_3 are related with each other and only one of them is independent. The two Majorana phases contributing to CP violation in LNV processes will manifest in I_2 and I_3 for neutrino mass matrices of types A_1 , A_2 , B_3 , B_4 and C . However, they will depend only on the single invariant I_3 for classes B_1 and B_2 . The Dirac phase contributing to CP violation in LNC processes depends upon I_1 . Hence, the three CP violating phases are not independent. There is only one independent physical phase in the mass matrix and it contributes to both LNC and LNV processes. However, such a phase cannot be labelled either Dirac or Majorana unambiguously since it contributes to the CP violation in both LNC and LNV processes. Hence, the distinction between Dirac and Majorana phases can not be maintained in the presence of two texture zeros. This is contrary to the conclusions reported in Ref. [13] where it has been claimed that the lone CP violating phase is of Dirac type and there are no Majorana phases.

4 Conclusions

We have calculated the CP-odd WB invariants both for LNC and LNV processes in a basis in which charged lepton mass matrix is diagonal. These invariants must vanish for CP invariance. We show that a neutrino mass matrix with three or more zeros gives CP invariance in LNC processes. However, it can give CP violation through the WB invariant I_2 in LNV processes if the three zeros are situated along a row of the mass matrix. The neutrino mass matrices with two texture zeros can, in general, be CP-violating if they are complex and if their phases are not fine tuned. The neutrino

mass matrices of class C in FGM scheme having $\mu - \tau$ symmetry contain no Dirac phase and show CP violation in LNV processes only. In general, all the seven classes of the neutrino mass matrices in FGM texture zero scheme have only one physical phase which gives rise to CP violation in both LNC and LNV processes and, hence, cannot be labelled as either Dirac or Majorana. The physical distinction between a Dirac and a Majorana phase cannot be maintained in the FGM texture zero scheme.
